

**The effect of different land-use practices  
on rangeland condition, herbaceous and  
seed bank composition – implications for  
land degradation and biodiversity  
management in semi-arid western  
rangelands of Southern Africa**

**M Coetzee & FP Jordaan**

**NW DACE**

**Scientific Technical Support Services**

# INTRODUCTION

- **Rangeland degradation**
- **Global Environmental Facility Desert Margins Program (GEF-DMP)**
- **Some indicators of rangeland condition: classification of herbaceous species according to the ecological rangeland condition concept, changes in botanical composition, bush density as an indicator of bush encroachment, bare soil and the composition of herbaceous species according to their life-form (annual, perennial etc.).**

# AIM

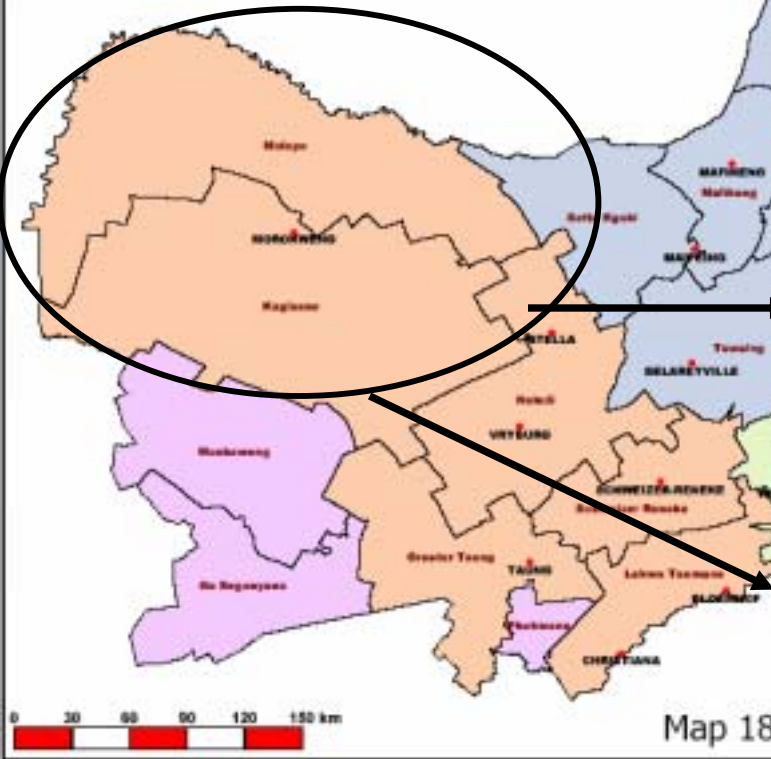

**Present herbaceous composition differences between Commercial (“conservation farmer”)-, Tribal and Reserve land uses, with special reference to degradation and diversity patterns within and between land uses, as a basis for understanding degradation and where possible, isolating indicators of degradation and diversity.**

- **Sites were selected on grounds of rangeland condition/“health”, not from the specific objectives of the respective land uses.**

# BOTSWANA

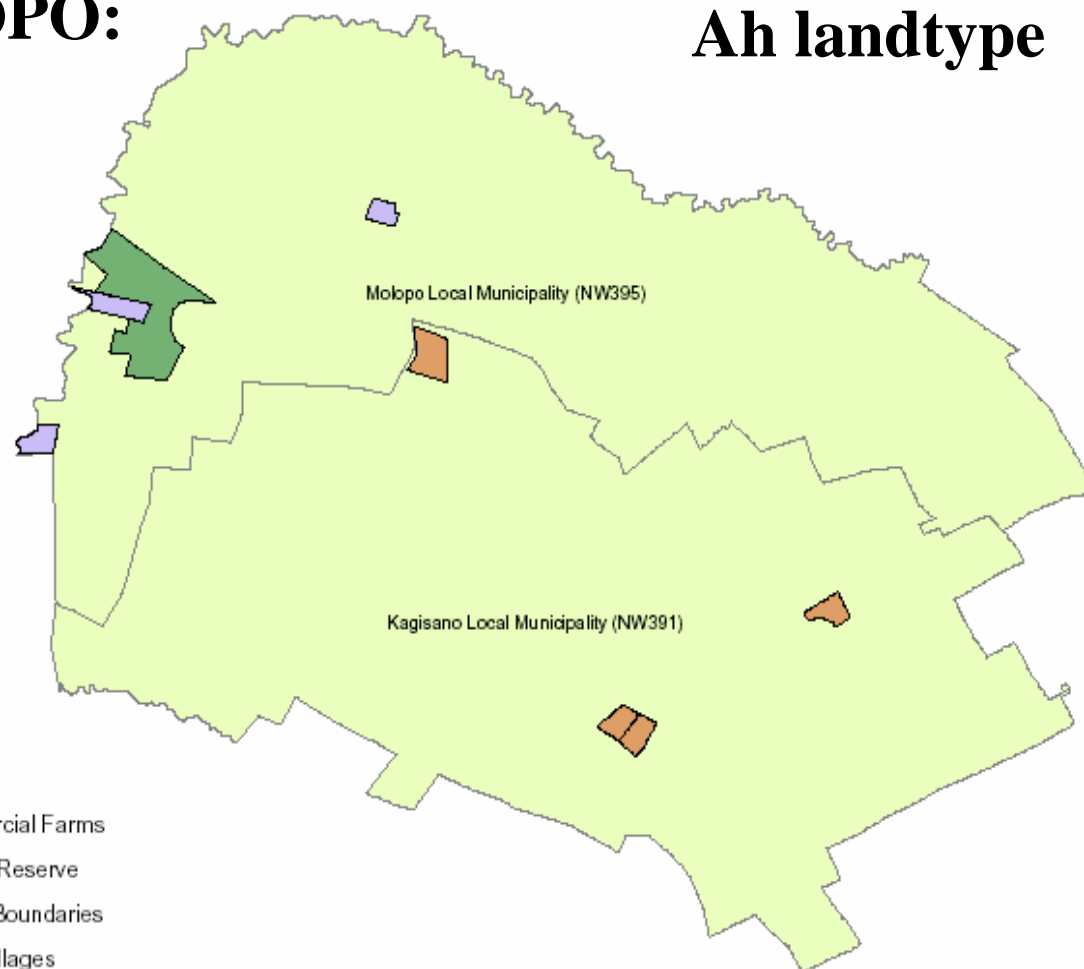

- Commercial land use: 3 replicates
- Reserve land use - 3
- Tribal land uses - 3

## MOLOPO:

## Ah landtype

### Legend

- Commercial Farms
- Molopo Reserve
- District Boundaries
- Tribal Villages

### Degradation gradient within each replicate:

- relative good and relative poor rangeland condition sites
- benchmark exclosures
- sites representative of management system

# MATERIAL AND METHODS

## 1. HERBACEOUS COMPOSITION:

- Descending point, nearest-plant method , PSION monitor until 98% of the variance has been explained

## 2. HERBACEOUS PRODUCTION:

- Dry weight rank method – (T'mannetje & Haydock)

## 3. HERBACEOUS QUALITY:

- Quality analysis for crude protein, metabolisable energy (ME), digestibility, minerals (phosphorus, magnesium and calcium), neutral detergent fibre (NDF) and acid detergent fibre (ADF).

## 4. SEEDBANK STUDIES:

- Samples up to 50mm collected in “open areas” as well as samples taken from beneath dominant woody component – mixtures kept apart

## 5. SOIL:

- Sampled from the open herbaceous and dominant woody component : topsoil (5-25 cm) & sub-soil strata (50-75cm)

## 6. WOODY COMPONENT:

- Bush density and woody species composition: TE/ha, number of individuals per species/ha and area coverage per species/ha
- Woody structural form

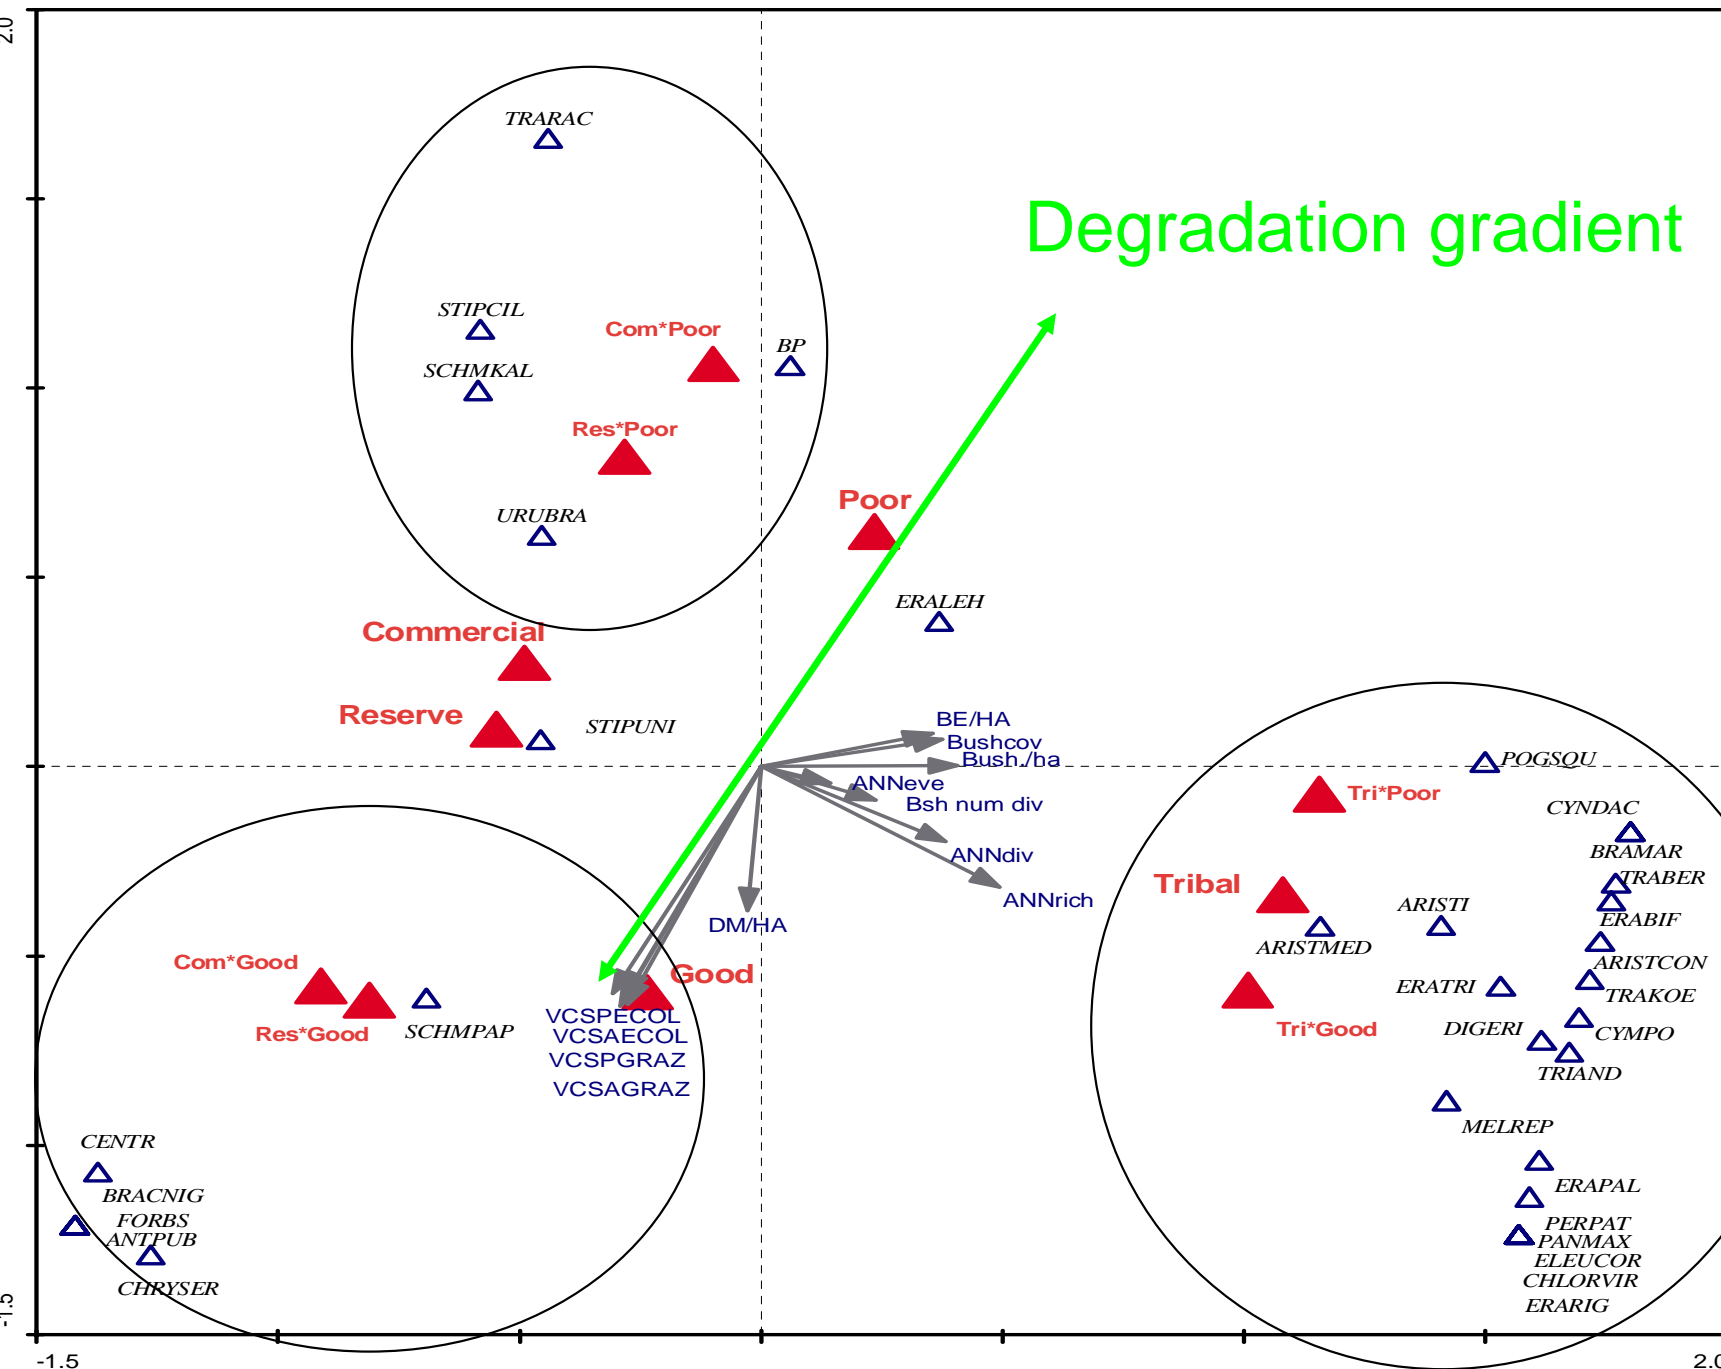

## 7. ANT SURVEYS: Sampled in 54 grids (sub-replicates) of 15 pitfalls each

# CONCLUSION

- Although rainfall events (non-equilibrium) are major driving factors of vegetation change in the Molopo, some management practices, irrespective of land use type, historically & currently do result in density-dependent processes (equilibrium), with the effect of degradation being masked by climatic events only up to a certain point, whereafter the system may reflect the longer-term degradation events due to losing its flexibility (resilience). If a shift towards a new domain has been reached, non-equilibrium events will not easily result in a transitional shift (flexibility) back.
- Events time-delayed, management impact observable later.
- In answer to the key objectives, this study found:
  1. Degradation gradient for the larger Molopo study area, including all land uses

2. A transitional shift in species composition for the entire Tribal land use, and Commercial/Reserve-Poor sites.
3. Seed bank composition studies corresponded with the herbaceous composition patterns.
4. Diversity indices associated with Tribal land use. Diversity patterns congruent between the herbaceous, woody and ant compositions.
5. Different herbaceous patterns at patch, paddock & landscape level.
6. Management impacts and rainfall showed “time-delayed” responses visible only at a later stage.
7. State-and-transition models may be most useful to describe vegetation dynamics pertaining to the Molopo rangelands – TPC’s.

# WAY FORWARD

- **Include other spectra of land uses along rangeland degradation gradient, and refine gradient, including different parameters (also animal norms etc.)**
- **Link different management aspects, where available, to biophysical data in “expert decision-making” model.**
- **Ensure effective multidisciplinary and multisectoral linkages to strengthen capacity, expertise and resources**
